HDL use

This register is inferred during synthesis and can also be explicitly instantiated.

Verilog Instantiation

```
// SB_DFF - D Flip-Flop.  
  
SB_DFF SB_DFF_inst (  
    .Q(Q),           // Registered Output  
    .C(C),           // Clock

SB_DFFE

D Flip-Flop with Clock Enable

Data D is loaded into the flip-flop when Clock Enable E is high, during a rising clock edge transition.

Default Signal Values

The iCEcube2 software assigns the following signal values to unconnected input ports:

Input D: Logic '0'

Input C: Logic '0'

Input E: Logic '1'

Note that explicitly connecting a logic '1' value to port E will result in a non-optimal implementation, since an extra LUT will be used to generate the logic '1'. It is recommended that the user leave the port E unconnected, or use the corresponding flip-flop without Enable functionality i.e. the DFF primitive.

Verilog Instantiation

```
// SB_DFFE - D Flip-Flop with Clock Enable.
```

```
SB_DFFE SB_DFFE_inst (  
    .Q(Q),           // Registered Output

        .E(E),          // Clock Enable
    );

// End of SB_DFFE instantiation

```

VHDL Instantiation

SB_CARRY

Carry Logic

The dedicated Carry Logic within each Logic Cell primarily accelerates and improves the efficiency of arithmetic logic such as adders, accumulators, subtractors, incrementers, decrementers, counters, ALUs, and comparators. The Carry Logic also supports a limited number of wide combinational logic functions.

The figure below illustrates the Carry Logic structure within a Logic Cell. The Carry Logic shares inputs with the associated Look-Up Table (LUT). The I1 and I2 inputs of the LUT directly feed the Carry Logic.. The carry input from the previous adjacent Logic Cell optionally provides an alternate input to the LUT4 function, supplanting the I3 input.

Block RAM Primitives

The iCE architecture supports dual ported synchronous RAM, with 4096 bits, and a fixed 16 bit data-width. The block is arranged as 256 x 16 bit words. The RAM block may be configured to be used as a RAM with data between 1-16 bits.

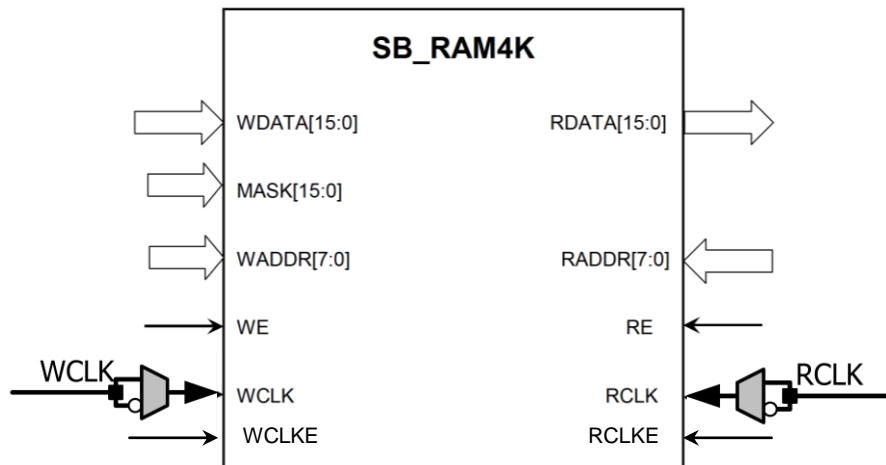

iCE65 Block RAM

Each iCE65 device includes multiple high-speed synchronous RAM blocks (RAM4K), each 4Kbit in size. A RAM4K block has separate write and read ports, each with independent control signals. Additionally, the write port has an Active-Low bit-line write-enable control; each write-port data bit has an individual write-enable control. By default, input and output data is 16 bits wide, although the data width is configurable using programmable logic and, if needed, multiple RAM4K blocks. The data contents of the RAM4K block are optionally pre-loaded during ICE device configuration.

RAM4K Naming Convention Rules

The SiliconBlue Technologies convention for the RAM4K primitives with negedge Read or Write clock is that the base primitive name is post fixed with N and R or W according to the clock that is affected, as displayed in the table below.

RAM Primitive Name	Description
SB_RAM4K	Posedge Read clock, Posedge Write clock
SB_RAM4KNR	Negedge Read clock, Posedge Write clock
SB_RAM4KNW	Posedge Read clock, Negedge Write clock
SB_RAM4KNRNW	Negedge Read clock, Negedge Write clock

RAM4K blocks have separate write and read ports, each with independent control signals.

The data contents of the RAM4K block are optionally pre-loaded during ICE device configuration. If the RAM4K blocks are not pre-loaded during configuration, then the resulting configuration bitstream image is smaller.

If an uninitialized RAM4K block is used in the application, then the application must initialize the RAM contents to guarantee the data value.

The following table lists the signals for both ports. Additionally, the write port has an active-Low bit-line write-enable control:

RAM4K Block RAM Signals		
Signal Name	Direction	Description
WDATA[15:0]	Input	Write Data input
MASK[15:0]	Input	Bit-line Write Enable input, active low
WADDR[7:0]	Input	Write Address input. Selects up to 256 possible locations
WE	Input	Write Enable input, active high
WCLK	Input	Write Clock input, rising-edge active
WCLKE	Input	Write Clock Enable input
RDATA[15:0]	Output	Read Data output
RADDR[7:0]	Input	Read Address input. Selects one of 256 possible locations
RE	Input	Read Enable input, active high
RCLK	Input	Read Clock input, rising-edge active
RCLKE	Input	Read Clock Enable input
INIT_0,,INIT_F	Verilog parameter	RAM Initialization Data. Passed using 16 parameter strings, each comprising 256 bits. (16x256=4096 total bits)

Write Operation

1. Supply a valid address on the WADDR[7:0] address input port
2. Supply valid data on the WDATA[15:0] data input port

To write or mask selected data bits, set the associated bit write MASK accordingly. For example, write operations on data bit Data[i] is controlled by the associated MASK[i] input: MASK[i] = 0: Enable write operations for data line Data[i]

- MASK[i] = 1: Mask write operations for data line Data[i]
- Enable the RAM4K write port (WE = 1)

3. Apply a rising clock edge on WCLK

Operation	WDATA[15:0] Data	MASK[15:0] Bit Enable	WADDR[7:0] Address	WE Enable	WCLK Clock	RAM Location
Disabled	X	X	X	X	0	No Change
Disabled	X	X	X	0	X	No Change
Write Data	D[i]	MASK[i]=0	WADDR	1	↑	RAM[WADDR[i]] = D[i]
Masked Write	X	MASK[i]=1	WADDR	1	↑	RAM[WADDR[i]] = No Change

Read Operation

The following table describes various read operations for a RAM4K block. All RAM4K read operations are synchronized to the rising edge of RCLK.

Operation	RADDR[7:0] Address	RE Enable	RCLK Clock	RDATA[15:0]
After configuration, before first valid Read Data operation	X	X	X	Undefined
Disabled	X	0	X	No Change
Read Data	RA	1	↑	RAM[RADDR]

To read data from the RAM4K block

1. Supply a valid address on the RADDR[7:0] address input port
2. Enable the RAM4K read port (RE = 1)
3. Apply a rising clock edge on RCLK

Default Signal Values

The iCEcube2 software assigns logic value '0' to all unconnected input ports, with the exception of the RCLKE and WCLKE ports.

The RCLKE and WCLKE ports are always enabled by default i.e. if left unconnected the software will automatically assign a logic value '1' to these ports. Note that explicitly connecting a logic '1' value to ports RCLKE and WCLKE will result in a non-optimal implementation, since an extra LUT will be used to generate the logic '1'. If the user's intention is to always maintain the clocks in an enabled state, it is recommended that these ports be left unconnected.

Note that the Read Enable (RE) and Write Enable (WE) ports are always disabled by default, since they are tied-off to logic '0' by the software, unless explicitly enabled by the user.

iCE40 Block RAM

Each iCE40 device includes multiple high-speed synchronous RAM blocks, each 4Kbit in size. The RAM block has separate write and read ports, each with independent control signals. Each RAM block can be configured into a RAM block of size 256x16, 512x8, 1024x4 or 2048x2. The data contents of the RAM block are optionally pre-loaded during ICE device configuration.

The following table lists the supported dual port synchronous RAM configurations, each of 4Kbits in size. The RAM blocks can be directly instantiated in the top module and taken through iCube2 flow.

Block RAM Configuration	Block RAM Size	WADDR Port Size (Bits)	WDATA Port Size (Bits)	RADDR Port Size (Bits)	RDATA Port Size (Bits)	MASK Port Size (Bits)

The SiliconBlue Technologies convention for the iCE40 RAM primitives with negedge Read or Write clock is that the base primitive name is post fixed with N and R or W according to the clock that is affected, as displayed in the table below for 256x16 RAM block configuration.

RAM Primitive Name	Description
SB_RAM256x16	Posedge Read clock, Posedge Write clock
SB_RAM256x16NR	Negedge Read clock, Posedge Write clock
SB_RAM256x16NW	Posedge Read clock, Negedge Write clock
SB_RAM256x16NRNW	Negedge Read clock, Negedge Write clock

SB_RAM40_4K

SB_RAM40_4K is the basic physical RAM primitive which can be instantiated and configured to different depth and dataports. By default, input and output data is 16 bits wide, although the data width is configurable using the READ_MODE and WRITE_MODE parameters. The data contents of the SB_RAM40_4K block are optionally pre-loaded during ICE device configuration.

IO Primitives

SB_IO

The SB_IO block contains five registers. The following figure and Verilog template illustrate the complete user accessible logic diagram, and its Verilog instantiation.

Default Signal Values

The iCEcube2 software assigns the logic '0' value to all unconnected input ports except for CLOCK_ENABLE.

Note that explicitly connecting a logic '1' value to port CLOCK_ENABLE will result in a non-optimal implementation, since an extra LUT will be used to generate the Logic '1'. If the user's intention is to keep the Input and Output registers always enabled, it is recommended that port CLOCK_ENABLE be left unconnected.

Verilog Instantiation

```
SB_IO IO_PIN_INST
(
    .PACKAGE_PIN (Package_Pin),           // User's Pin signal name
    .LATCH_INPUT_VALUE (latch_input_value), // Latches/holds the Input value
    .CLOCK_ENABLE (clock_enable),          // Clock Enable common to input and output
    clock
    .INPUT_CLK (input_clk),                // Clock for the input registers

defparam IO_PIN_INST.PULLUP = 1'b0;        // By default, the IO will have NO pull up. This
                                              // parameter is used only on bank 0, 1, and 2.

                                              // Default is rising edge
defparam IO_PIN_INST.IO_STANDARD = "SB_LVCMOS";
                                              // Other IO standards are supported in bank 3
                                              // only: SB_SSTL2_CLASS_2, SB_SSTL2_CLASS_1,

                                              // SB_MDDR8, SB_MDDR4, SB_MDDR2 etc.
```

Input and Output Pin Function Tables

Input and Output functions are independently selectable via PIN_TYPE [1:0] and PIN_TYPE [5:2] respectively. Specific IO functions are defined by the combination of both attributes. This means that the complete number of combinations is 64, although some combinations are not valid and not defined below. Note that the selection of IO Standards such as SSTL and LVCMOS are not defined by these tables.

Input Pin Function Table				
#	Pin Function Mnemonic	PIN_TYPE[1:0]		Functional Description of Package Pin Input Operation
1	PIN_INPUT	0	1	Simple input pin (D_IN_0)
2	PIN_INPUT_LATCH	1	1	Disables internal data changes on the physical input pin by latching the value.
3	PIN_INPUT_REGISTERED	0	0	Input data is registered in input cell
4	PIN_INPUT_REGISTERED_LATCH	1	0	Disables internal data changes on the physical input pin by latching the value on the input register
5	PIN_INPUT_DDR	0	0	Input 'DDR' data is clocked out on rising and falling clock edges. Use the D_IN_0 and D_IN_1 pins for DDR operation.

Output Pin Function table						
#	Pin Function Mnemonic	PIN_TYPE[5:2]				Functional Description of Package Pin Output Operation
1	PIN_NO_OUTPUT	0	0	0	0	Disables the output function
2	PIN_OUTPUT	0	1	1	0	Simple output pin, (no enable)
3	PIN_OUTPUT_TRISTATE	1	0	1	0	The output pin may be tristated using the enable
4	PIN_OUTPUT_ENABLE_REGISTERED	1	1	1	0	The output pin may be tristated using a registered enable signal
5	PIN_OUTPUT_REGISTERED	0	1	0	1	Output registered, (no enable)
6	PIN_OUTPUT_REGISTERED_ENABLE	1	0	0	1	Output registered with enable (enable is not registered)
7	PIN_OUTPUT_REGISTERED_ENABLE_REGISTERED	1	1	0	1	Output registered and enable registered
8	PIN_OUTPUT_DDR	0	1	0	0	Output 'DDR' data is clocked out on rising and falling clock edges
9	PIN_OUTPUT_DDR_ENABLE	1	0	0	0	Output data is clocked out on rising and falling clock edges
10	PIN_OUTPUT_DDR_ENABLE_REGISTERED	1	1	0	0	Output 'DDR' data with registered enable signal
11	PIN_OUTPUT_REGISTERED_INVERTED	0	1	1	1	Output registered signal is inverted
12	PIN_OUTPUT_REGISTERED_ENABLE_INVERTED	1	0	1	1	Output signal is registered and inverted, (no enable function)
13	PIN_OUTPUT_REGISTERED_ENABLE_REGISTERED_INVERTED	1	1	1	1	Output signal is registered and inverted, the enable/tristate control is also registered.

Syntax Verilog Use

```
defparam my_generic_IO.PIN_TYPE = 6'b{Output Pin Function, Input Pin Function};
```

Output Pin Function is the bit vector associated with PIN_TYPE[5:2] and Input Pin Function is the bit vector associated with PIN_TYPE[1:0], resulting in a 6 bit value PIN_TYPE[5:0]

Example

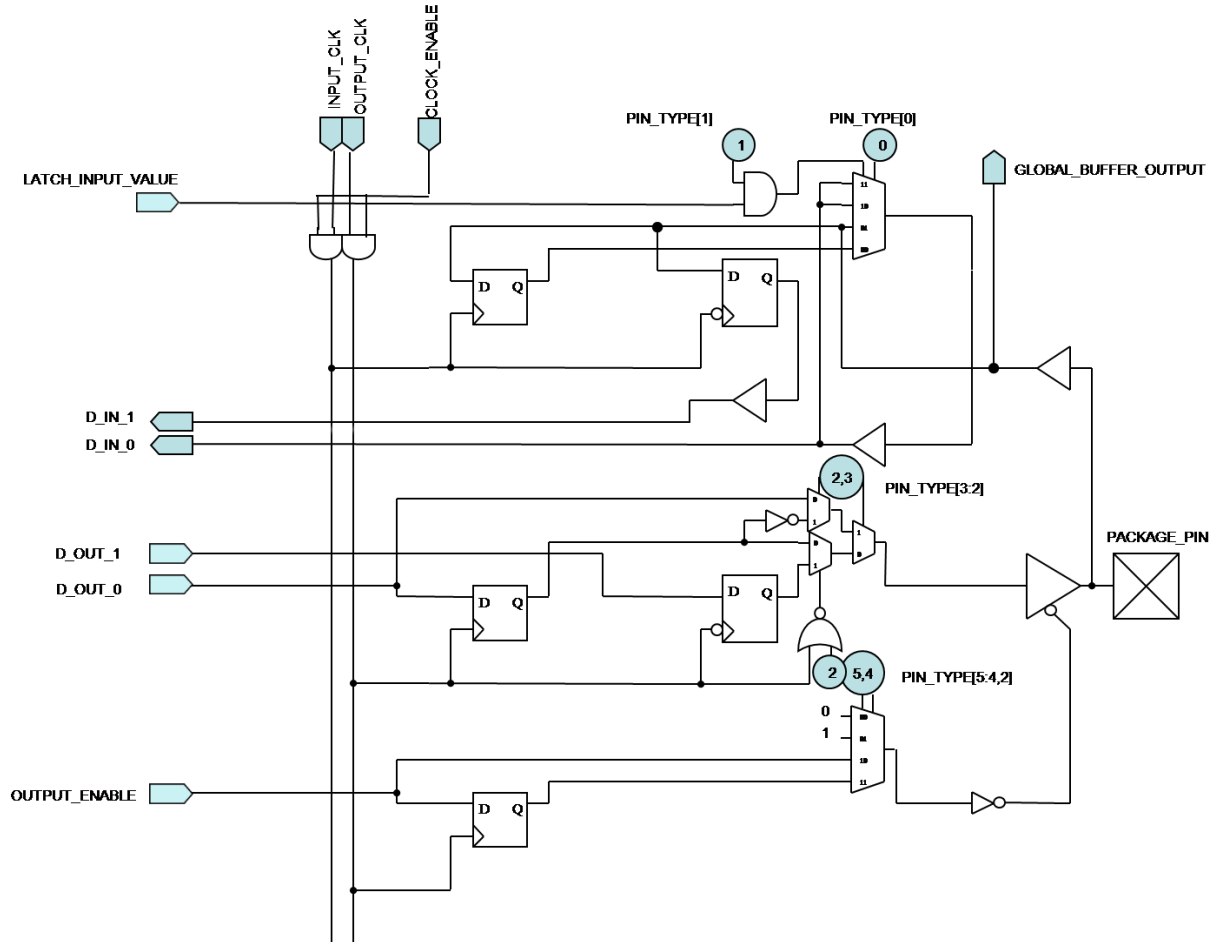

```
defparam my_DDR_IO.PIN_TYPE = 6'b110000; //PIN_TYPE[5:2] = 1100, PIN_TYPE[1:0] = 00
```

This creates a DDR IO pin whereby the input data is clocked in on both the rising and falling clock edges.

The output 'DDR' data is clocked out on rising and falling clock edges, and the output may be tri-stated, using the enable port of the SB_IO.

PLL Primitives

The Phase Lock Loop (PLL) function is offered as a feature in certain devices of the iCE65 and iCE40 device family . .

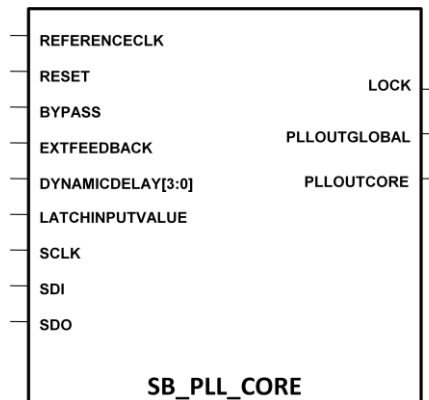

It is strongly recommended that the configuration of the PLL primitives be accomplished through the use of the PLL Configuration tool that is offered as part of the iCEcube2 software.

iCE65 PLL Primitives

There are 3 primitives that represent the PLL function in the iCEcube2 software viz. SB_PLL_CORE, SB_PLL_PAD, and SB_PLL_2_PAD. A short description of each primitive and its ports/parameters is provided in the following sections.

SB_PLL_CORE

The SB_PLL_CORE primitive should be used when the source clock of the PLL is driven by FPGA routing i.e. when the PLL source clock originates on the FPGA or is driven by an input pad that is not in the bottom IO bank (IO Bank 2).

Ports

REFERENCECLK: PLL source clock that serves as the input to the SB_PLL_CORE primitive.

PLLOUTGLOBAL: Output clock generated by the PLL, drives a global clock network on the FPGA.

PLLOUTCORE: Output clock generated by the PLL, drives regular FPGA routing. The frequency generated on this output is the same as the frequency of the clock signal generated on the PLLOUTGLOBAL port.

LOCK: Output port, when HIGH, indicates that the signal on PLLOUTGLOBAL/PLLOUTCORE is locked to the PLL source on REFERENCECLK.

EXTFEEDBACK: External feedback input to PLL. Enabled when the FEEDBACK_PATH parameter is set to EXTERNAL.

DYNAMICDELAY: 4 bit input bus that enables dynamic control of the delay contributed by the Fine Delay Adjust Block. The Fine Delay Adjust Block is used when there is a need to adjust the phase alignment of PLLOUTGLOBAL/PLLOUTCORE with respect to REFERENCECLK. The DYNAMICDELAY port controls are enabled when the DELAY_ADJUSTMENT_MODE parameter is set to DYNAMIC.

RESET: Active low input that asynchronously resets the PLL.

BYPASS: Input signal, when asserted, connects the signal on REFERENCECLK to PLLOUTCORE/PLLOUTGLOBAL pins.

LATCHINPUTVALUE: Active high input, when enabled, forces the PLL into low-power mode. The PLLOUTGLOBAL/PLLOUTCORE pins are held static at their last value. This function is enabled when the parameter ENABLE_ICEGATE is set to '1'.

SCLK, SDI, SDO: These pins are used only for internal testing purposes, and need not be instantiated by users.

ice40 PLL Primitives

There are 5 primitives that represent the PLL function in the iCEcube2 software viz. SB_PLL40_CORE, SB_PLL40_PAD, SB_PLL40_2_PAD, SB_PLL40_2F_CORE and SB_PLL40_2F_PAD for the ice40 device family. A short description of each primitive and its ports/parameters is provided in the following sections.

It is strongly recommended that the configuration of the PLL primitives be accomplished through the use of the PLL Configuration tool that is offered as part of the iCEcube2 software.

SB_PLL40_CORE

The SB_PLL40_CORE primitive should be used when the source clock of the PLL is driven by FPGA routing i.e. when the PLL source clock originates on the FPGA or is driven by an input pad that is not in the bottom IO bank (IO Bank 2).

Ports

REFERENCECLK: PLL source clock that serves as the input to the SB_PLL40_CORE primitive.

PLLOUTGLOBAL: Output clock generated by the PLL, drives a global clock network on the FPGA.

PLLOUTCORE: Output clock generated by the PLL, drives regular FPGA routing. The frequency generated on this output is the same as the frequency of the clock signal generated on the PLLOUTGLOBAL port.

LOCK: Output port, when HIGH, indicates that the signal on PLLOUTGLOBAL/PLLOUTCORE is locked to the PLL source on REFERENCECLK.

EXTFEEDBACK: External feedback input to PLL. Enabled when the FEEDBACK_PATH parameter is set to EXTERNAL.

DYNAMICDELAY: 7 bit input bus that enables dynamic control of the delay contributed by the Fine Delay Adjust Block. The Fine Delay Adjust Block is used when there is a need to adjust the phase alignment of PLLOUTGLOBAL/PLLOUTCORE with respect to REFERENCECLK. The

DYNAMICDELAY port controls are enabled when the DELAY_ADJUSTMENT_MODE parameter is set to DYNAMIC.

RESETB: Active low input that asynchronously resets the PLL.

BYPASS: Input signal, when asserted, connects the signal on REFERENCECLK to PLLOUTCORE/PLLOUTGLOBAL pins.

LATCHINPUTVALUE: Active high input, when enabled, forces the PLL into low-power mode. The PLLOUTGLOBAL/PLLOUTCORE pins are held static at their last value. This function is enabled when the parameter ENABLE_ICEGATE is set to '1'.

SCLK, SDI, SDO: These pins are used only for internal testing purposes, and need not be instantiated by users.

Device Configuration Primitives

SB_WARMBOOT

iCE FPGA devices permit the user to load a different configuration image during regular operation. Through the use of the Warm Boot Primitive, the user can load one of 4 pre-defined configuration images into the iCE FPGA device.

Note that this Warm Boot mode is different from the Cold Boot operation, which is executed during the initial device boot-up sequence.

The selection of one of these 4 images is accomplished through 2 input signals, S1 and S0. In order to trigger the selection of a new image, an additional signal, BOOT, is provided. It should be noted that this signal is level-triggered, and should be used for every Warm Boot operation i.e. every time the user wishes to load a new image into the device.

The successful instantiation of this primitive also requires the user to specify the address locations of the 4 images. These addresses should be specified in the iCEcube2 software as per the Warm Boot Application Note.

Verilog Instantiation

```
SB_WARMBOOT my_warmboot_i (
    .BOOT (my_boot),           //Level-sensitive trigger signal
    .S1 (my_sel1),             //S1, S0 specify selection of the configuration image
    .S0 (my_sel0)
);
```
